1 Introduction

1.1 Course management

Tasks were divided among team members in weekly status meetings. In the same meetings the progress of tasks was monitored, and the next set of assignments were decided.

1.2 Group roles & responsibilities

The course work was shared between team members. Team member responsibilities, roles and affected hosts are outlined in Table 1 (p. 1616). Each team member had a host to apply patches and mitigations for certain vulnerabilities or misconfigurations. Such tasks are compared to a task list found from *Appendix 1: Service Catalog creditbanken.vle.fi*. Each task is represented via *Risk id* number which can be compared to the task list. In addition to the patches, certain team members also had a task to write about different subjects around future work, implementation of additional security controls and other parts of the document like the chapter you are currently reading on. Those tasks are mentioned in *Future work*, *Implementation of additional Security Controls* and *Additional work* of the table. *Implementation of additional Security Controls* and *Future work* are evidenced in 5 and 7 respectively in the document.

To help the reader, mapping of given tasks to the *actual* work done should be straight forward. For example, the following Table 1 contains a subject called *AppLocker* (*Implementation of additional Security Controls* column) which can be found from chapter 5.1 AppLocker. In addition, Risk ids in the *Patching and mitigations* (*Risk id*) columns along with *Future work*, *Implementation of additional Security Controls* and *Additional work* columns follows the following color scheme and explanations: green (task is done and documented) and red (task is incomplete and not fully documented). Also keep in mind that it is the duty of the person responsible for the given task to complete the color scheme and is by default marked as incomplete (red).

1.3 Company network diagram

The Figure 1 outlines the company network structure:

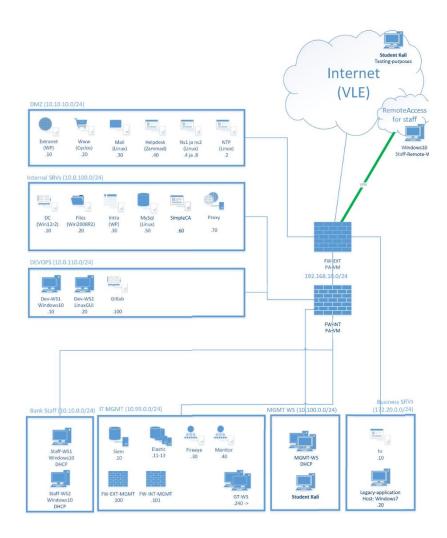

Figure 1. Network diagram

2 Description of Bank's Assets, Threats, and Risks

In this chapter, we discuss the various assets that the Creditbanken bank possesses and how the network has been segmented. Moreover, we identify the various threats to these assets and the vulnerabilities which cause the threats. Finally, we assess the impact of vulnerability to the critical asset and calculate the risk. In the following chapter, we identify ways to reduce the risk to an acceptable level via implementation of various security controls.

The threats to any organization's infrastructure include both outside and internal threats. The insider threats can be a company's own disgruntled or poorly trained employees while the outside threats could include cyber criminals, competitors, or hacktivists. The threats faced could be spear phishing infection with malware. In this case the victims are sent an exploit document with enticing content and after the victim opens the file, the malware is installed into the victim's computer. The other tactic could be webmail access via spearphish in which case a domain is registered spoofing a webmail service and email is sent to target to reset their passwords. When the recipient visits the fake login page and enters the credentials, they are stolen. Another tactic is the infection with malware via strategic web compromise and finally is the access through internet facing servers. In this case, Network Reconnaissance is performed to find vulnerable software and initial compromise is leveraged to access other systems and move deeper into the victim network. These are just some tactics that are employed by the attackers to gain access to your system by utilizing the known vulnerabilities.

2.1 Assets

The bank's assets include physical and hardware assets and the software assets. The network diagram in the previous section (chapter 1.3) shows the various assets that the IT Infrastructure of the bank possesses. These assets include information assets in the form of databases, software assets in the form of web applications and various security solutions, hardware assets in the form of Firewalls, services, and intangibles such as the bank's reputation and intellectual property. The network has been segmented into various zones with each zone further comprising workstations, firewalls, and other security solutions.

DMZ

This zone consists of an Extranet, Cyclos, Mail server, Helpdesk, NS1 and NS2 and NTP server. The Extranet is a private, secure network aimed at sharing business information with partners, suppliers, and customers etc. It is implementation in DMZ (DeMilitarized Zone) gives streamlined business process management, high data security and increased customer satisfaction. Cyclos is banking software normally utilized by banks as a payment platform for mobile banking and enabling branchless banking. The Mail server in the said DMZ is CentOS Linux based. Zammad helpdesk software is a free helpdesk system which connects all your communication channels, email, chat, telephone and easily grant user rights and reporting. NS1 and NS2 and public master and slave Linux based DNS servers while NTP is the Network Time Protocol server that enables synchronization of system clocks from desktops to servers.

Internal SRVs

Internal services include DC, which is the Active Directory and DNS resolver, file server for the provision of Windows File and Storage Services for employees, intranet for staff's internal use, MySQL server in the role of user's database and devices, Certificate Authority for provision of Certificate Management, and proxy server.

DevOps

The DevOps segment comprises of two Windows and Linux based Dev workstations and a Linux based Git version control.

Bank Staff

The bank staff subnet contains two windows 10 based workstations which have been reserved for staff windows usage.

IT MGMT

The IT Management segment consists of a SIEM which is Security Incident and Event Management. SIEM allows us to perform real time monitoring of security events along with their analysis when doing the root cause analysis. It also allows us to collect logs and perform security data tracking. It automates many of the event detection and incident response processes. The SIEM implemented here is an Elastic search SIEM.

The IT Management section also contains three Elastic Search nodes. Elastic search is a distributed, NoSQL JSON database. The interaction with ELK is done via REST APIs and is known for its speed of search and scalability. Another important device in the IT Management section is the FireEye. FireEye Endpoint Security is an Endpoint protection platform which combines conventional anti-virus software with advanced real-time monitoring and detection. The PRTG is a network traffic monitoring solution also deployed in IT Management. Lastly, there are two External and Internal Firewalls at the Network edge for traffic filtering.

MGMT WS

The Management Workstations comprise of Student Kali workstation and DHCP workstation. The Student Kali workstation is the one used for accessing other machines in the network and the DHCP workstation is used for Dynamic IP Assignment to various instances of the machine.

Business SRVs

Finally, the Business Services workstation comprises of HR workstations and Legacy application windows workstation.

2.2 Threats Confronting the Company

The Bank in question is a highly sought-after cyber target and thus demands strict policies to be put in place to preserve the user's information, bank's software assets, intellectual property, technical documentation along with the IT infrastructure that it possesses. In the present situation, with the rapid digitalization and cloud migration of all companies and banks assets, particularly in the post-COVID world, financial institutions such as banks are more prone to cyber-attacks and the threats and risks being faced by the bank are on the rise. Therefore, these risks and threats must be considered because in the banking sectors, significant sums of money are involved and in the event of compromise, the disruption to the financial institution and the economy itself can be considerable.

For the hardware-based assets, the threats can be building fire, theft, elevated temperature etc. while for the software-based assets including the databases and web applications, these threats include Ransomwares, security concerns with the remote work, Cloud based cyber-attacks, social engineering, and supply chain attacks, among others. A description of threats is detailed Table 2 found below.

Asset	Threat
Customer Accounts Database,	Cyber criminals: Ransomware, Social
Employee Accounts Data-	Engineering, Phishing, Password At-
base, Elastic Search, MySQL	tack

	tual Property Trademark	

Table 2. Asset types, assets and threats

2.3 Vulnerabilities

Vulnerabilities are the weaknesses in the IT infrastructure that can be exploited by an attacker to conduct a successful cyber-attack. The vulnerabilities can be network vulnerabilities, operating system vulnerabilities, human and process vulnerabilities. To identify vulnerabilities in the network, we use various tools such as NMAP, Linpeas, Winpeas, Nessus and Greenbone (see Table 4). We run scans on various network devices and these scans output the vulnerabilities in the network devices. Table 3 illustrates the various vulnerabilities identified in the network based on the scans as well as the impact assessment of the threats posed by these vulnerabilities.

Sr. #	Asset (Device Name)	Vulnerability	CVE number	Short Description
1	Extranet, WWW, Mail	Polkit Out-of-Bounds Read and Write Vulnerability	CVE-2021-4034	Local privilege escalation in pkexec due to incorrect han-dling of argument vector
2	Helpdesk, Mail	Linux Kernel Race Condition Vulnerability	CVE-2016-5195	Race condition in mm/gup.c in the Linux kernel 2.x through 4.x before 4.8.3 allows local users to gain privileges by leveraging incorrect handling of a copy-on-write (COW) feature to write to a read-only memory mapping
3	Extranet	Linux Kernel Privilege Esca- lation Vulnerability	CVE-2022-2588	A use-after-free flaw was found in route4_change in the net/sched/cls_route.c filter implementation in the Linux kernel. This flaw allows a local user to crash the sys-

				h
				tem and possibly lead to a lo-
				cal privilege escalation prob-
				lem.
				Race condition in mm/gup.c
				in the Linux kernel 2.x
				through 4.x before 4.8.3 al-
				lows local users to gain privi-
				leges by leveraging incorrect
				handling of a copy-on-write

				A race condition was found in
				the way the Linux kernel's
				memory subsystem handled
				the copy-on-write (COW)
	Elasticsearch 1 & 2 &			breakage of private read-only
9	3	dirtycow2	CVE-2016-5195	memory mappings

				A local privilege escalation vulnerability was found on polkit's pkexec utility. The
				pkexec application is a setuid
				tool designed to allow un-
				privileged users to run com-
				mands as privileged users ac-
				cording to predefined
				policies. The current version
				of pkexec does not handle
				the calling parameters count
				correctly and ends up trying
				to execute environment vari-
				ables as commands. An at-
				tacker can leverage this by
				crafting environment varia-
				bles in such a way it will in-
				duce pkexec to execute arbi-
				trary code. When
				successfully executed the at-
				tack can cause a local privi-
				lege escalation given unprivi-
				leged users administrative

Table 3. Vulnerabilities

2.4 Risk Management

Risks in a banking system can be either operational or strategic. Among the top operational risks for a bank is the Cyber risk. The others are third-party risks, internal and external frauds, business disruptions and system failures. Particularly in the context of a post-pandemic world, the cyber threats such as Ransomwares and Phishing have become widespread, and the threat actors leverage organizations' weaknesses in the IT infrastructure to perpetuate serious cyber-attacks. Therefore, risk management is an integral part of a Bank's Cyber security strategy.

In risk management, Asset, Threat and Vulnerability management are brought together. In this exercise, all assets, threats and vulnerabilities are bound to cyber security area and issues with physical security (access control to facilities, natural disasters, et cetera and safety (employee safety like black mailing)) are out of scope.

The aim is to attach suitable threats to each asset. Each asset may have several threats and the same threat can occur in several different assets (Table 2. Asset types, assets and threats). Threats are associated with all appropriate vulnerabilities (Table 3. Vulnerabilities) in the same style as assets and threats. All matching vulnerabilities are added to each asset-threat combination, thus forming a matrix showing all combinations of asset, threat and vulnerability (combination of "Table 2. Asset types, assets and threats" and "Table 3. Vulnerabilities" is embedded to full list of vulnerabilities (Appendix 1). Measure of risk now reflects the overall effect of the risk on the company.

Risks are assessed based on the following rules. Machines are valued with the impact level from 1 to 4 (1 = low, 4 = critical) based on how critical the machine is for the company's network and operations. The impact level (this can be seen in each machines chapter), and risk criticality give us the threat level. Threat level tells us how crucial it is to mitigate or fix the issue in the environment.

3 Technical security testing

This section describes methods the internal security team used to find flaws in the company's technical security posture. The purpose of technical security testing was to figure out the company's current technical issues, vulnerabilities, and misconfigurations across different hosts. Such findings were then managed accordingly, namely patched, mitigated, classified as a future work, or marked as an accepted risk. Also, such findings and the person responsible for acting accordingly were documented to an Excel sheet (see *Appendix 1: Service Catalog creditbanken.vle.fi.*) on the columns *Vulnerability* and *Responsible person*, respectively.

The network diagram which outlines hosts in the company network can be evidenced from Figure 1 (page 17).

3.1 Summary

Serious and numerous flaws were identified in the company's technical security posture. Such flaws required immediate attention to be fixed and are outlined in the document's sections 2 and 4. Such flaws included but were not limited to remote code execution on numerous hosts due to such hosts missing critical system and service updates. For example, Files server was vulnerable to Eternal Blue (CVE-2017-0143) and Gitlab server to CVE-2021-22205 which both allowed executing code in the machine from an unauthenticated standpoint. In addition to flaws that were due to missing security patches, there were also several ones found that were derived from poor application misconfigurations. Namely, HR server was exposing its database credentials in publicly and easily available file in its web server. In addition, there were guessable credentials in the *creditbanken.vle.fi* domain in the Windows Active Directory for a user *at* that belongs to domain admins group, a group that controls the whole domain. In addition to more severe security flaws, several minor misconfigurations were identified. For example, the company's authoritative DNS server (ns2) was allowing unauthorized DNS Zone Transfers (see Nidecki 2019) to public parties. In addition, several hosts were exposing its service names and corresponding version numbers.

3.2 Approach

The approach to find security flaws on the company hosts was to combine both automation and manual testing. The security team was provided with information about hosts in the company network (see Figure 1 (p. 17)). Such information included things like what services are running on what hosts. However, some key information such as which ports were open on which hosts was yet to be discovered. Therefore, the team decided to port scan every IP subnet to generate a list of open ports associated with the hosts in the network. After this, the hosts and their corresponding ports were scanned with a vulnerability scanner and then, found vulnerabilities were technically validated.

In addition to using purely automation, manual security testing was also applied depending on the host and corresponding services offered. For example, Windows Active Directory environment was reviewed for common misconfigurations like users with excessive privileges or bad practice security hardenings through querying LDAP. In addition, for example hosts that were offering a web service were manually scanned for publicly available files through a technique called directory brute forcing. Indeed, many bad practice configurations and vulnerabilities were discovered manually.

To summarize the approach outlined above:

Automation

- 1. Scan and map every subnet for hosts to discover which ports are open on the host.
- 2. Run a vulnerability scanner against the before generated list.
- 3. Verify findings.

Manual testing

- 1. Scan and map every subnet for hosts to discover which ports are open on the host.
- 2. Apply manual security testing approach for given services.

3.3 Tooling

To achieve the forementioned results, certain security testing tooling was used. The Table 4 specifies used tooling, more specifically tool's name, purpose, and source:

Name	Purpose	Source
Rustscan	Portscanner	GitHub (see Rustscan the mod-
		ern port scanner 2022)
Nessus Essentials	Vulnerability Scanner	Tenable web site (see Tenable
		for Education n.d.)

Table 5. Summary of security findings

4 Technical security hardening

This section describes what methods the company used to patch and remediate found technical security flaws to ensure feasible security posture.

4.1 Project management

An Excel workbook has been used as the project management tool for the updating and patching phase, which serves as a basis for defining the criticality of the work, dividing responsibility and controlling the workflow.

Basic server information such as IP address, name, IDs and passwords, etc. has been recorded in Excel on the computer tab (see *Appendix 2: Network Catalog creditbanken.vle.fi*). In addition to the basic information, the computer tab has an assessment of the criticality of the machine to the company's operation in the "impact level" column. At the beginning of the work, we ran operating system updates to machines where it was possible, that is, the machine's operating system is not in EoF status, the status of the update is marked in the Updated column.

During the web scan, we collected a list of vulnerabilities in project management Excel on the Vulnerability tab. Vulnerabilities were collected e.g., Nessus reports, linPEAS and winPEAS checks and other tools mentioned earlier in the Tool section. We also calculated the severity of the vulnerability in the criticality column. For each vulnerability found, a responsible person was named whose task it was to patch or mitigate that vulnerability.

In the last step, a person was assigned responsibility for the machines, whose task was to examine the installation of the machine in more detail and to correct possible installation errors and vulnerabilities. The person responsible is named in the Assigned to column. The duties of the person responsible also included recording the descriptions of the chapter Service updates and patches.

The urgency of the patch is determined by the criticality of the machine and the severity of the vulnerability. The most critical servers with high vulnerabilities are patched or mitigated first.

Patching urgency is determined based on the severity of the machine and the vulnerability. The most critical servers with major vulnerabilities are patched or controlled first.

4.2 General Workflow

At the beginning we ran through scans on every machine, by using winpeas/linpeas script inside the machine and Nessus from the network against each machine. After the preliminary scanning, we updated all the systems we could.

Some of the Linux systems are updated nicely to the latest possible build for that release path like CentOS7, as it is still on support. Then there are other Linux machines with CentOS 6 or 8. support for those operating systems ended some time ago. These systems we were able to update only partially. Some components installed on these machines are no longer updated to support these discontinued operating systems. After updating all the systems as far as possible we ran those scans again and got the listing of the weaknesses that cannot be mitigated easily just by updating operating systems.

Some of these old operating systems can still be updated by installing packages manually. But then there are those old Windows operating systems. All of them cannot be updated at all, as the operating system is not activated and even the activated system would need long term support agreement with Microsoft to get any kind of updates for these. This problem concerns Windows 7 and Windows Server 2008R2 systems, but also Windows Server 2012R2 is old enough to be difficult to update without support agreements with Microsoft. Windows machines also suffer from poorly configured Group Policies that prevent all connection to Microsoft's Update services to get updates there. And there has not been any installation of local repository or cache to offer Windows updates to machines connected to the company's network.

Updated Servers and status

All the CentOS 7 machines were updated to the latest version. CentOS 8 is already in the End-of-Life state, so there we faced some difficulties to update operating system. Some of the OS components are not What servers were updated and what are not and why...

4.3 Service updates and patches

Many of the services/applications were installed to the machines as a separate package and could not be a general update process.

All Linux servers have been tried to patch the common security holes found by the Greenbone scanner (*Greenbone*, 2021). Repairs have been made to the servers, which includes repairs, among other things:

- removing old kernels
- SSL/TLS secure configuration
- Verifying SSH and ensuring sufficient encryption strength.
- removed TLSv1.0 and TLSv1.1

Using a configuration management tool like Ansible (see Ansible, 2023), Puppet (See Puppet, 2023) or Chef (see Chef, 2023) could have made sense to centralize Linux patching. These tools provide a centralized and automated approach to managing configurations and updates across multiple Linux servers. By utilizing these tools, we would have been able to install patches and updates more easily to all Linux servers in a controlled and coordinated manner, while ensuring that all servers are constantly patched and up to date. In addition, these tools provide auditing and reporting capabilities that facilitate tracking and monitoring of the repair status of the server base and quickly fix any anomalies or vulnerabilities.

4.4 Patches and fixes by server

Because automatic scanners such as Nessus and Greenbone (*Greenbone*, 2021) are not able to effectively find mistakes made during installation, such as bad and repeated passwords and forgotten files. We also try to examine the files and configurations related to the services of the servers and report and fix them. The problems found were reported and mitigated as much as possible.

4.4.1 Extranet Server

Impact: Estimated impact medium 2: Possible Loss of same sensitive customer data.

Figure 2. Extranet patching and remediations

Notes regarding the server

Since CentOS 8 is End of Life, mirrors were changed to vault.centos.org where they will be archived permanently the server has been updated to the last possible version. The vulnerabilities mentioned in the project Excel have been fixed.

The server's firewall is enabled. In the firewall, traffic to the internet is allowed only for http and https services. Subnets IT MGMT and MGMT WS connected to trusted networks, so ssh, SIEM and FireEye services work. In the Palo Alto firewall, the traffic of the management networks is more precisely restricted per service and port. Access to the servers is blocked from other servers in the same subnet.

Since CentOS 8 is no longer supported, automatic update cannot be enabled.

Unnecessary packages have been cleaned from the server.

4.4.2 WWW Server

Impact: Estimated impact Critical 4: A critical service for the bank's operation, significantly affects the bank's ability to operate and contains highly confidential data. High risk of misuse.

OS versioning	Service number-	Service descrip-	Firewalling (Source	More details about
	ing (after up-	tion	hosts, Protocol +	connections
	dates)		Port)

			(1733)	capsa printing siv
			Outhound fallowed	
			Outbound (allowed	
			to)	
			Elastic nodes (TCP,	Auditbeat agent,
			9200)	Filebeat agent

The following Figure 3. WWW Server patching and remediations specifies e.g., vulnerabilities and corresponding criticality, description, patch, mitigation and whether it is specified as accepted risk.

Figure 3. WWW Server patching and remediations

Notes regarding the server

As CentOS 6 is in End of life, it should be updated Immediately. All the most important services are out of date (Tomcat, Java, MySQL) also due to the aging of the operating system, i.e., the services are no longer updated according to the normal update process. The services must be updated manually from the packages. There is a considerable risk of the service breaking down, which may be too big a risk because there is no more detailed information about installing the service.

Weak password in MySQL is changed. Cyclos and Sendmail configured to use authentication. Cyclos password requirements are updated.

4.4.3 NTP Server

Impact: Estimated impact medium 2: Possible attack vector for several other servers.

OS versioning	Service number- ing (after up- dates)	Service descrip- tion	Firewalling (Source hosts, Protocol + Port)	More details about connections
CentOS Linux re-	chrony 3.4-1.el7	Server provides	Inbound	
lease 7.9.2009		time synchroni-	Management	Management connec-

		work		
			Outbound (allowed	
			to)	
			Elastic nodes (TCP,	Auditbeat agent,
			9200))	Filebeat agent
			Chronyd (UDP,123)	NTP service

Patching & mitigations

The following Figure 4. NTP server patching and remediations specifies e.g., vulnerabilities and corresponding criticality, description, patch, mitigation and whether it is specified as accepted risk.

Figure 4. NTP server patching and remediations

Notes regarding the server

The server's firewall is enabled. In the firewall, Subnets IT MGMT and MGMT WS connected to trusted networks, so ssh, SIEM and FireEye services work. In the Palo Alto firewall, the traffic of the management networks is more precisely restricted per service and port. Access to the servers is blocked from other servers in the same subnet, except ntp-protocol is allowed. Unnecessary packages have been cleaned from the server.

Vulnerabilities ID 4 and ID 5 were marked as accepted risks because these would require OS update to mitigate.

4.4.4 Intranet Server

Impact: Estimated impact High 3: Possible Loss of sensitive customer data and banks internal documentation.

OS versioning	Service number-	•	Firewalling (Source	
	ing (after up- dates)	tion	hosts, Protocol + Port)	connections
	dutesy

Patching & mitigations

FigureFigure 77. Gitlab patching and remediations specifies e.g., vulnerabilities and corresponding criticality, description, patch, mitigation and whether it is specified as accepted risk.

Figure 77. Gitlab patching and remediations

Notes regarding the server

Since CentOS 8 is End of Life, mirrors were changed to vault.centos.org where they will be archived permanently the server has been updated to the last possible version. The vulnerabilities mentioned in the project Excel have been fixed.

The server's firewall is enabled. In the firewall, traffic to the internet is not allowed. Subnets IT MGMT and MGMT WS connected to trusted networks, so ssh, SIEM and FireEye services work. In the Palo Alto firewall, the traffic of the management networks is more precisely restricted per service and port. Access to the servers is blocked from other servers in the same subnet, except ssh connection from 10.0.110.10 and 20 are allowed connect to Gitlab via SSH.

Since CentOS 8 is no longer supported, automatic update cannot be enabled.

Unnecessary packages have been cleaned from the server.

4.4.7 NS1-2

Impact: Estimated impact medium 2: Name services are important for everyday operations of the organization, but loss of them does not deny accessibility of resources via IP-address. Configuration files on many of the organization's servers contain either IP-based or name-based addresses making assessment of the impact difficult should the name services be lost.

OS versioning	Service number- ing (after up- dates)	Service descrip- tion	Firewalling (Source hosts, Protocol + Port)	More details about connections

Figure 88. NS1-2 patching and remediations

Notes regarding the server

Since CentOS 7 is End of Life, mirrors were changed to vault.centos.org where they will be archived permanently the server has been updated to the last possible version. The vulnerabilities mentioned in the project Excel have been fixed. The server's firewall is enabled. Since CentOS 8 is no longer supported, automatic update cannot be enabled. Unnecessary packages have been cleaned from the server.

Vulnerabilities

Service: Bind9

Details

Updated conf files to prevent zone transfer.

Service: Named Bind version number was hidden from name server configuration files. Mitigation was confirmed by querying the version number. NS2 DNS zone transfer was limited to only NS1 by creating a list of trusted servers. Confirmed by testing DNS query from NS1 which works but fails from student Kali.

Firewalling

Host based firewalling was configured to only allow SSH from management network. DNS services were allowed for all hosts in the environment.

4.4.8 FireEye

Service: FireEye EDR, Appliance image was updated from 5.1.1.953432 -> 5.3.1.982205.

Description: FireEye Endpoint Security (HX) is an endpoint security solution that combines antivirus (EPP), next-generation antivirus (NGAV), and EDR.

Agents: Agents were installed on Staff-WS2 (10.10.0.101) and Extranet-server (10.10.10.10)

OS versioning	Service number- ing (after up-	Service descrip- tion	Firewalling (Source hosts, Protocol +	More details about connections
	dates)		Port)	
FireEye	N/A	Endpoint security	Inbound	
v.5.3.1.982205		solution	0.0.0.0/0 (HTTP	WordPress
			(80), HTTPS (443))	
			Management	Management connec-
			VLANs (SSH (22))	tions
			FireEye EDR (TCP,	FireEye Agent
			80)	
			Outbound (allowed	
			to)	

Verification

Tested FireEye malware scan by installing EICAR test virus file to Extranet-server. Initiated scan to extranet, but scan failed for some reason. Logs did not provide any valuable information about why the scan failed. After multiple failed scans, EICAR was installed to Staff-WS2 server. Then executed malware scan to staff server, scan was completed successfully but it did not find vulnerabilities. It seems that servers have some protection that detected EICAR test file and made it not function properly.

Patching & mitigations

The Figure 9. FireEye patching and remediations specifies e.g., vulnerabilities and corresponding criticality, description, patch, mitigation and whether it is specified as accepted risk.

Figure 9. FireEye patching and remediations

4.4.9 Windows Active Directory (DC01)

Impact: Estimated impact Critical 4: Possible Loss of sensitive customer or employee data.

OS versioning	Service number- ing (after up- dates)	Service descrip- tion	Firewalling (Source hosts, Protocol + Port)	More details about connections
Windows Server	N/A	Server provides	Inbound	Allowed to all AD re-
2012R2		Windows Active	Files, Bank Staff	lated services from
		Directory Do-	subnet, MGMT WS	Files server and from
		main Services	subnet (SMB, RPC	subnets Bank Staff and
		(ADDS)	interfaces (135, 139	MGMT WS.
			and 445), Kerberos	
			(88), DNS (53)	
			Outbound (allowed	Auditbeat agent,
			to)	Filebeat agent
			Elastic nodes (TCP,	
			9200)	

Patching & mitigations

The Figure 1010 specifies e.g., vulnerabilities and corresponding criticality, description, patch, mitigation and whether it is specified as accepted risk.

Figure 1010. AD patching and remediations

Notes regarding the server

Firewalling

Server should be allowing only inbound traffic to Windows Active Directory specific services. Server should allow outbound Elastic Beat connections to the Elastic server.

Vulnerabilities

Server suffers from certain non-critical vulnerabilities or misconfigurations as seen in the before Figure. Risk with ID 95 was deemed the highest severity misconfiguration due to the ease to obtain Domain Admin equivalent credentials in the domain. Risks with ID 14 and 15 are deemed as accepted risks since they are unlikely to be exploited (ID 14) or the actual business impact is not high (ID 15). Namely risk 14 requires that attacker has obtained *man-in-the-middle* type of position in the network. On the other hand, risk 15 allows obtaining a Kerberos ticket with RC4 encryption as opposed to AES. Risk id 65 was fixed in order to prevent several attacks from working that require a control of service account (an AD account with an SPN). Since computer accounts satisfy this requirement, the *Machine Account Quota* AD attribute was set to 0.

MachineAccountQuota

MachineAccountQuota setting was changed from 10 to 0. By default, In the Microsoft Active Directory, members of the authenticated user group can join up to 10 computer accounts in the domain. This value is defined in the attribute *ms-DS-MachineAccountQuota* on the domain-DNS object for a domain. After changing value to 0, users must have explicit permissions in Active Directory to join computers

to

a

domain.

4.4.10 File and Storage services (Files)

Impact: Estimated impact medium 2: Possible Loss of sensitive customer or employee data.

OS versioning	Service number-	Service descrip-	Firewalling (Source	More details about

FigureFigure 1515. specifies e.g., vulnerabilities and corresponding criticality, description, patch, mitigation and whether it is specified as accepted risk.

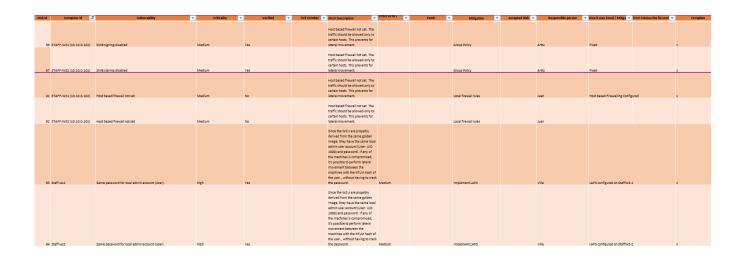

Figure 1515. Staff-WS1 patching and remediations

Notes regarding the server

General

FireEye agent was deployed to the workstation. Sysmon and Winlogbeat installed.

Vulnerabilities

Server suffers from certain non-critical vulnerabilities or misconfigurations as seen in the above Figure.

SMB Signing disabled

(ID 66) Server message block signing, or SMB signing for short, is a Windows feature that allows you to digitally sign at the packet level. SMB signing is needed because digital signing helps recipients to confirm the origin and authenticity of the incoming packet. SMB signing was disabled in Staff-ws2, and we enabled the setting.

Same password for local admin account

Since the workstations are probably derived from the same golden image, they have the same local admin user account (User: RID 1000) and password. If any of the machines is compromised, it is possible to perform lateral movement between the machines with the NTLM hash of the user, without having to crack the password. LAPS was configured on Staff-ws1 server to mitigate.

4.4.15 SimpleCa

Impact: Estimated impact critical 4: Possible Loss of certification. Affects availability of services and integrity of data.

OS versioning	Service number-	Service descrip-	Firewalling (Source	More details about

Figure 1919. PRTG patching and remediations

Notes regarding the server

Firewalling

Server should be allowing only inbound traffic to Windows Active Directory specific services. Server should not initiate any connections and are therefore blocked.

4.5 Firewalling

4.5.1 Palo-Alto Firewall:

Firewalling is done to prevent the Bank's network from unauthorized access to the servers and rest of the network devices. It further segments the network into trusted, untrusted and semi-trusted zones and monitors and logs all connections. Therefore, the primary function of a firewall will be to create a border and inspect the packets that enter and leave the network. The inspection is done through creation of firewall rules based on source IP addresses, destination IP addresses and application.

Types of Firewalls:

Firewalls can be either hardware or software based. The major types of firewalls are Packet Filtering, Proxy, Stateful, Next Generation and Unified Threat Management Firewalls. There is another type

of Firewalling named Host-based Firewalling which has been performed individually for each host and is explained after this section. For our network, we have used the Palo Alto Networks Next Generation Firewalls that can perform packet inspection at the application level. Further, in our Bank's network, there are two Firewalls; the first one is the External Firewall and the second one is the Internal Firewall. Each of these firewalls are explained in the section below: -

Firewall External:

The External Firewall acts as the Perimeter Firewall and prevents Private networks' access to known malicious sites. It also prevents unwanted traffic from entering the network. There is also a Demilitarized Zone (DMZ) associated with the External Firewall that is intended to be an additional layer of security for an organization's internal network. The bank's external and customer facing servers and services such as DNS, mail, proxy, NTP and bank's website are in the DMZ. The DMZ provides a buffer between the internet and bank's internal private network. The main benefits of a DMZ include Enabling Access Control, Preventing Network Reconnaissance and Blocking IP Spoofing.

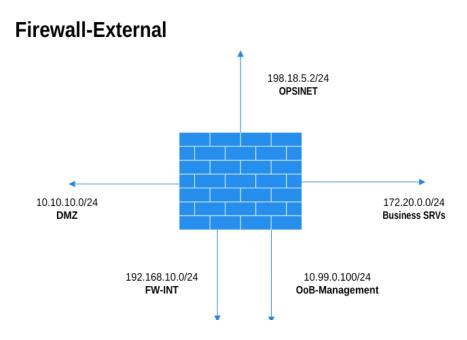

Figure 2020. External firewall

The network diagram for the External Firewall is given above (Figure 20). The first interface named OPSINET is the one connected to the internet. This interface is the one that is visible to the outside world. The second interface is the Management interface that is assigned the Management IP. This IP is the one that is used by machines in the network for accessing the Firewall. The third interface is named Firewall Internal which connects the External Firewall to the Internal Firewall. The remaining two zones are named the DMZ and Business Servers. The purpose of DMZ has been explained above. In the case of our Bank's network, it contains the Extranet Server, the Web Server, the Mail Server, the Helpdesk, the DNS servers and the NTP server. The Business Servers contain the HR machine and the Legacy Windows Application.

The Palo Alto Firewall is accessible via both command line SSH and web HTTPS. The setting of Firewall policies and configuration changes can be done via both CLI and GUI. The first step we took towards hardening Palo Alto firewall was that we upgraded the current firewall version from **9.0.5** to **11.0.0**. Version upgradation serves to automatically take care of any old misconfiguration and vulnerabilities. The upgradation of PA Firewall just follows a series of commands from the command line and is also possible from the web interface.

Firewall Configurations:

The first step in configuring the firewall for necessary control over the traversing traffic is that the various interfaces of the firewall are assigned IP addresses and then these interfaces are assigned to specific zones which in our case are DMZ, BUSINESS SRVs, FW-INT, OPSINET and FW-EXT. The next step is the creation of Address Groups and Addresses which is done in the Objects section of PA Firewall configurations.

Afterwards comes the creation of Security Profiles. Before starting out to create the security policies, it is essential to create at least one security profile to be used in all your security rules. The first Security Profile to be created is The Antivirus Profile in which various protocols such as SMTP, POP3, IMAP, HTTP2 and FTP have various actions associated with them. These actions include allow, drop, alert, reset-client, reset-server and reset-both. This profile can also perform Packet Capture. The

next is the Anti-Spyware Profile which operates based on the severity level of the threat. If the threats are Critical, Medium or High we can associate packet capture and either reset client, server or both. Similar actions can be taken for Low or Informational level threats. Similarly, relevant actions can be taken for DNS policies. The next profile is Vulnerability Protection, more commonly known as IPS/IDS. Here the threats can be classified based on their severity level as Critical, Medium, High or Low and Informational.

Afterwards, there is URL Filtering Profile in which the filtering is done based on URL categories which can be Ransomware, Phishing sites, adult sites, religious sites and Gambling sites. Then comes the File Blocking Profile in which the PA Firewall can block files based on their extensions. The last is the WildFire Analysis Profile in which based on the file name, file type and application, the file is forwarded to the Public Cloud. Finally, we create the Security Profile Group in which all these security profiles are merged, and default is named for the Security Profile Group.

NAT:

Network Address Translation or more commonly known as NAT / PAT is an essential part of Firewall configurations that is required by hosts in the network to reach the internet and vice versa. In our network, NAT is performed from OPSINET to DMZ as an Inbound NAT and from DMZ to OPSINET as an outbound NAT. The private IP Addresses being used are both class-A, class-B and class-C. While configuring NAT, we give the NAT policy a necessary name, the source zone, the destination zone, the source address, destination address and the type of translation that can be either NAT, PAT or dynamic IP and Port. There is also one-to-many NAT done for traffic originating from FW-INT and going to the Internet but primarily it is the one-to-one NAT that has been performed for flow of traffic between the firewall interfaces.

Security Policies:

Next is the creation of Security Policies. Two Security Policies, i.e., Intrazone and Interzone have been created by default. We have created the following rules for our External Palo Alto Firewall.

- The known Malicious, High-risk and Bulletproof IP addresses have been blocked from Untrust to Inside Network. Similarly, their access from inside Network to Outside has also been blocked.
- The Management interface of the External Firewall has been granted access from the Management Workstations subnet inside the Internal Firewall via SSH, HTTP and HTTPS.
- The Direct Access from Internet to Firewall Internal Zone has been blocked by any IP address.
- The access from Internet to DMZ has been allowed.
- The access from DMZ to Internet has also been allowed.
- The traffic between the DMZ and Business Servers has been restricted.
- Some specific Management Applications have been granted the access

Monitoring:

The traffic that flows across the various Firewall interfaces can be monitored with the help of Palo Alto Firewall. In the policies section of the PA-Firewall, there is a possibility to count the hits that the Firewall experiences for a certain policy rule. Furthermore, in the Monitor section, there are logs for data traffic between zones with the time stamp, packet-size, port, source IP and destination IP. There are similar logs for threats, URL filtering, wildfire submissions along with the report generation capability.

Zero-Trust:

Overall, with the help of this Firewall, we have implemented a zero-trust architecture in the Bank's enterprise network. Zero-trust refers to a Cybersecurity approach in which every stage of the digital interaction is validated and the principle of "Never Trust, Always Verify" is adopted using the policy of least access. We have implemented Zero-trust in our architecture using deny-all as the default policy and then allowing the traffic flow for specific applications and between certain zones and network devices.

Firewall Internal:

The Internal Firewall performs the Inter-zone traffic flow control between the zones in the internal network. The diagram (Figure 21) for the Internal Firewall indicates how the interfaces have been assigned to various zones.

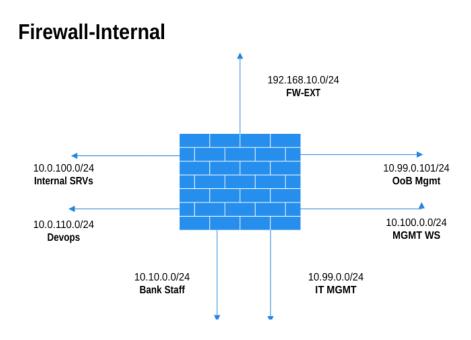

Figure 2121. Internal firewall

The first interface is connected to the External Firewall which receives the traffic from the Internet, the DMZ and Business Servers. The second interface is the OoB Management which refers to 10.99.0.101 IP address for accessing the Internal Firewall from the Management Workstations. The third zone is the Internal Servers which contains Active Directory. Active Directory is the directory service for windows-based machines. The Active Directory serves as the role of Domain Controller. It performs the authentication and authorization of all users in Windows domain network. In other words, it performs the system administration of windows-based machines. This zone also contains the Files Server which is a windows machine and is based on the ftp protocol and provides a shared disk space for storing files that can be accessed via workstations. There is also an Intranet server for sharing information, tools and collaboration within the organization. MySQL Server is a Linux based CentOS-7 operating system machine that serves as database for the whole network. There is also Simple CA which is the Certificate Authority for storing, signing and issuing Digital Certificates. The

last is the proxy server which provides as intermediary between the client requesting the service and the server providing that resource.

The next zone is Devops which contains a Windows based machine, a Linux based machine and Gitlab. The Bank Staff zone contains two DHCP machines which are both windows based. The Management Workstation contains the student kali which is the machine for accessing the rest of the network along with a DHCP server for assigning the users dynamic IP addresses. Lastly, the most important is the IT Management subnet which comprises of the Firewall Management IPs, the Elastic SIEM for logs monitoring, the Fireeye, the Monitor machine which is the PRTG and three Elastic Search storage nodes.

Firewall Configurations and Security Policies:

Similar to the FW-EXT, the Internal Firewall configuration begins with creating the network interfaces and assigning them the IP addresses. It then assigns these interfaces to various zones, each of which has been explained above. Network Address Translation is not required for the Internal Firewall since the NAT has already been performed for the External Firewall. The Security Profiles for Anti-virus, Anti-spyware, Vulnerability Protection, URL Filtering, File Blocking and Wildfire area created just like previously.

Using the Internal Firewall, inter-zone access has been restricted except for specific applications and machines on need-basis. The following security policies have been created using the Internal Firewall: -

- The Management Workstation zone is allowed access to every other zone since the student kali desktop needs to access every machine in the Bank's network.
- Two-way access between the Devops zone and Bank Staff zone is restricted.
- The access between Internal Servers and Devops is restricted.
- The access between Internal Servers and Bank Staff is restricted.

- All the machines in the Internal Servers subnet are allowed to access every other machine in the IT Management subnet except for Firewalls.
- The Devops machines subnet and the IT Management zone are also restricted in access.
- The IT Management zone has restricted access for all other zones in the network.

Regarding the monitoring, the logs for the relevant security policies can be monitored through the hit counts and from the monitoring section of the Palo Alto Firewall. Furthermore, the hit count is also available for every security policy in the Policies section of the PA-Firewall. The logs come with time stamps for the occurrence of event, packet-size, application port, source IP and destination IP address.

4.5.2 Host-Based Firewalling:

A host-based firewall is the one installed directly on a personal computer or machine rather than the network. If some malicious worms, viruses or malware are not able to be caught by the PA Network based Firewall, then the host-based firewall serves the purpose of protecting the computer machine individually. The primary reason for doing Host-based firewalling is to implement the **Principle of Least Privilege (POLP).** It is a security strategy where users are given only a minimum access to perform their job functions and to minimize the risk of unauthorized access to sensitive information or systems. It helps improve overall security and prevents unauthorized access to sensitive information.

In the case of our bank's network, the PA-Firewall is restricting the traffic between subnets / zones but inside each subnet, the host-based firewall is configured to restrict the flow of traffic between

various servers and hosts. The details of host-based firewalling for each server are given in the Servers section of the report (4.4).

Linux Machines:

In case of Linux machines, the host-based firewalling is achieved by writing Access Control Lists (ACLs) which are either:

- Iptables
- Firewalld
- Uncomplicated Firewalls (UFW)

Using these firewall tools, the machine can block incoming and outgoing traffic based on the source and destination IP addresses, ports, and a range of IP addresses. In the case of our network, inside each zone, we have configured a host-based firewall. This firewall blocks the incoming connections from all other hosts or servers in the zone and allows only the ssh, http and https connections. This offers more granular control and protection against internal threats compared to the Network based firewall.

Windows Machines:

The windows machines used in our network are either 2012R2, 2008R2 or Windows 10 machines. They use windows firewall with advanced security as the default firewall. Using this firewall, one can create both inbound and outbound rules by giving the source and destination IP address and the TCP / UDP ports. The major ones in our network are the Files Server, the Active Directory, the monitor machine and the Windows 7 legacy application machine in the Business SRVs zone.

In the case of these machines, the host-based firewalling has been used to restrict incoming traffic from other hosts in the same subnet. Inter-zone access has been limited by the Palo-Alto Firewall.

The default policy for these machines has been set to DENY ALL and the only allowed connections are ssh, http and the https connections.

5 Implementation of additional Security Controls

This section defines what additional security controls the company implemented.

5.1 AppLocker

Theory

AppLocker is a tool/feature of Windows that limits the applications and files user can run in Windows installation. These include executable files, scripts Windows installer files, dynamic-link libraries (DLLs), packaged apps, and packaged app installers (Microsoft, 2023).

Information is the only and the most precious thing (asset) to secure in many companies and organizations. That is why we must ensure that only approved users can access that information. Access control technologies like Active Directory Rights Management Services (AD RMS) and access control lists (ACLs), eases the control user accesses.

AppLocker is made to help control user or groups to delete or transmit sensitive information out of organization if user intentionally or unintentionally runs malicious software. AppLocker mitigates this risk of security breaches caused by malicious software execution by restricting the file4s that users can run.

AaronLocker

AaronLocker is a toolset for helping AppLocker and Windows Defender Application Control (WDAC) (Microsoft, 2023) creation and maintenance of a strict and robust application control. The toolset uses a small number of PowerShell scripts to do the job (Margosis, 2023).

Technical implementation

Environments where we can use AppLocker/AaronLocker functionality can be found in Table 6.

Version	Can be configured	Can be enforced	Available rules	Notes
			Packaged apps, Executable,	
Windows Server 2012 R2	Yes	Yes	Windows Installer, Script, DLL	
			Executable, Windows Installer,	Packaged app rules will
Windows Server 2008 R2 Standard	Yes	Yes	Script, DLL	not be enforced.
			Executable, Windows Installer,	Packaged app rules will
Windows 7	Yes	Yes	Script, DLL	not be enforced.
			Packaged apps, Executable,	
Windows 10	Yes	Yes	Windows Installer, Script, DLL	

Table 6. Windows system where to use AppLocker.

5.2 Local Administrator Password Solution (LAPS)

Microsoft provides a solution for managing local administrator passwords called Local Administrator Password Solution (LAPS). LAPS provides a secure method for automatically generating and managing unique passwords for local administrator accounts on Windows computers and storing them securely in Active Directory. LAPS also allows for password policy enforcement and auditing of password changes (Microsoft, n.d.).

5.3 Sysmon

Sysmon is a Windows system service and device driver that provides advanced system monitoring capabilities. It can be used to collect detailed information about various system activities, such as process creation, file creation, network connections, and registry modifications, and then log this information to the Windows event log. Sysmon can be configured to generate highly customizable event logs that provide detailed information about system events, and can be used for various use cases, such as intrusion detection, malware analysis, and forensic investigations (Microsoft, 2021).

Sysmon was installed in combination with Winlogbeat to StaffWS-2 to send Windows system logs to Kibana.

5.4 Microsoft System Center Configuration Manager (SCCM) and Windows Server Update Services (WSUS)

WSUS and SCCM are both IT management products by Microsoft. Both have their own unique capabilities to ensure endpoints are in optimal condition and compliant to policy. Both products are considered legacy products and are designed for Windows OS and Microsoft products.

WSUS stands for Windows Server Update Service (Microsoft, 2023). It is a default role that can be installed on a Windows server. WSUS is also free to use. WSUS is used to distribute patches and updates to endpoints on the network. WSUS uses push-style patching. One of the limitations with WSUS is that there is no way of knowing if the endpoint is missing a patch. Determining if a patch is missing from and endpoint is the IT administrator's responsibility. WSUS can be deployed on-prem or through Azure.

SCCM stands for System Center Configuration Manager (Microsoft, 2023), and it is included in the Microsoft Endpoint Configuration Manager (MECM) SCCM offers more feature for endpoint management like health monitoring, remote access, OS deployment, endpoint discovery, protection, and reporting. SCCM is more valuable when combined with WSUS. Unlike WSUS, SCCM is not free to use but requires a license.

WSUS and SCCM are capable effectively of managing and monitoring Microsoft environments when they are used together. Non-Windows OS management and monitoring is an issue however for these products. SCCM can patch Mac OS with add-ons, but for Linux it is not a valid option.

5.5 SCCM / WSUS in target company for assignment

- WSUS will be used for Windows updates: WSUS is primarily designed to manage Windows updates, so it is best to use it for this purpose. This can include critical security patches, nonsecurity updates, and service packs.
- 2. SCCM will be used for third-party updates: While WSUS is designed for Windows updates, SCCM can manage both Windows and third-party updates.
- 3. Each update will be tested in a controlled environment to ensure that they do not cause any issues.
- 4. Updates and compliance will be monitored. It is important to monitor the status of updates and ensure that devices are compliant with the organization's policies. This can include running regular compliance reports and tracking failed updates.
- 5. WSUS and SCCM maintenance: To ensure that WSUS and SCCM function effectively, it is essential to perform regular maintenance tasks like backup and recovery, database optimization, and security updates.

5.6 Center for Internet Security (CIS) Benchmark (level 1)

While performing the vulnerability scanning for the Bank's network and followed by the security testing and technical security hardening, we have tried to implement the CIS Security Controls. CIS controls are a list of high-priority and very effective defensive actions that provide a first do starting point for every enterprise looking to improve its cyber defense. By adopting these controls, organizations can prevent a major chunk of cyber-attacks. The latest version 8 of these security controls is enumerated below:

- 1. Inventory and Control of Enterprise Assets
- 2. Inventory and Control of Software Assets
- 3. Data Protection
- 4. Secure Configuration of Enterprise Assets and Software
- 5. Account Management
- 6. Access Control Management
- 7. Continuous Vulnerability Management
- 8. Audit Log Management

- 9. Email and Web Browser Protection
- 10. Malware Defenses
- 11. Data Recovery
- 12. Network Infrastructure Management
- 13. Network Monitoring and Defense
- 14. Security Awareness and Skills Training
- 15. Service Provider Management
- 16. Application Software Security
- 17. Incident Response Management
- 18. Penetration Testing

During our technical security hardening, we implemented some of these controls. These include Inventory and Control of Enterprise Assets. This has been done in section 2.1, which lists the inventory of various assets the Bank possesses. The other control implemented is the Software Assets which has also been explained in the section 2.1 that provides a list of Software based assets for the company and the threats they pose, Secure Configuration of Enterprise Assets and Software, Access Control Management which has been done through Network and Host-based Firewalling, Continuous Vulnerability Management which entails performing a vulnerability analysis through Nessus and Greenbone scanner and then fixing those vulnerabilities in order to prevent the threats, Email and Web Browser Protection has been done through updating the email servers and DNS filtering and blocking unnecessary file types, Malware Defenses through Sandboxing, Network Monitoring and Defense and Incident Response Management using a SIEM and PRTG.

6 Verification and Analysis of Threat Exposure after Security Controls Implementation

In this chapter, we look at verifying and analyzing exposure to a threat after security controls have been implemented in systems.

Based on the vulnerabilities collected in Excel (see Appendix 1) and the Nessus reports, we had created a list of vulnerabilities. Based on this list and reports, selected patches were implemented to patch the vulnerabilities. After the implementation of the security control measures, the Nessus scanner was run again, which was used to evaluate the effectiveness of the implemented control measures in mitigating the detected vulnerabilities. When doing each patch, we always try to ensure the reliability of the patch, either with a scanner or by checking manually. The patching method is usually recorded in the Excel workbook as well. At this point, it must be stated that some of the vulnerability fixes were possibly not recorded in the Excel workbook, especially at the point when we went through the servers manually. The final scan and analysis results revealed the following findings:

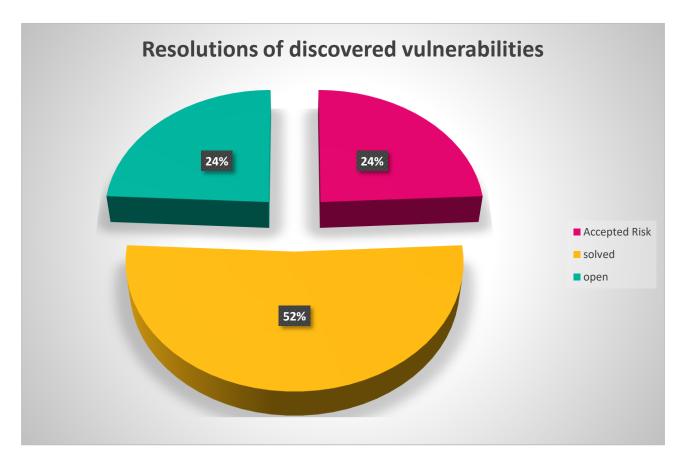

Figure 2222. Resolutions of discovered vulnerabilities

52% of vulnerabilities fixed: This indicates that more than half of the vulnerabilities identified in the vulnerability assessment were successfully fixed and the associated risks have been reduced. Patching means installing software updates or vendor-supplied patches to fix known vulnerabilities in software applications or operating systems.

24% of vulnerabilities were considered acceptable: This means that a quarter of the identified vulnerabilities were considered acceptable based on the risk assessment. Acceptable vulnerabilities are vulnerabilities that cannot be fixed or mitigated for several reasons, such as technical limitations, operational effects or lack of expertise. The aim is to monitor these systems with the help of Elastic SIEM and FireEye systems.

24% of vulnerabilities were still open: This suggests that a sizable portion of identified vulnerabilities remained unpatched and related security holes still exist. This is partly due to the fact that not all members of the group participated fully in the exercise and the servers assigned to them were partially or completely not processed.

Out of all the vulnerabilities found by Nessus (see Figure 2323), the priority was to fix Critical and High vulnerabilities. Other classifications such as medium and low were discussed within the framework of the sufficiency of time and expertise.

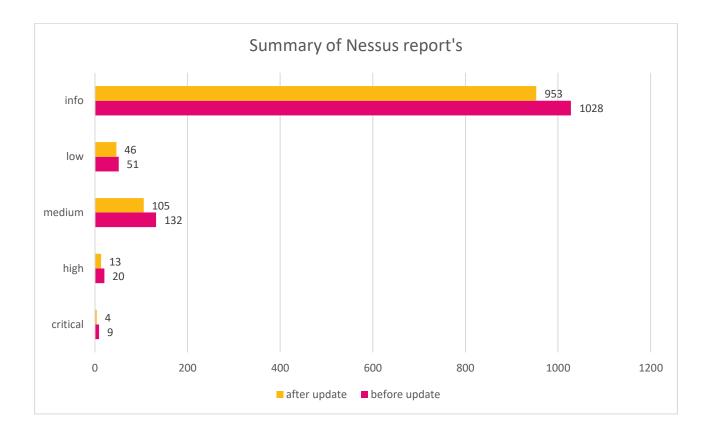

Figure 2323. Summary of Nessus reports

Based on the findings, although a significant part of the vulnerabilities was successfully fixed and were considered acceptable, there is room for improvement in fixing the remaining open vulnerabilities.

In summary, verification and analysis of threat exposure following the deployment of security controls revealed that while progress has been made in remediating and remediating acceptable vulnerabilities, additional efforts are needed to mitigate remaining open vulnerabilities.

7 Future work

The following section defines the future work to be done to enhance the company's security posture.

7.1 Update old Windows and Linux servers.

The company employs some End of Life (EOL) servers or servers that will soon drop the support for system updates. Since such systems do not receive security updates, they are prone to have critical security vulnerabilities. The possibility of updating the following servers should be examined and upgrading them if possible. In the same note, such servers should employ the newest service updates as when the servers are updated. The upgrades should be done before May 2023. The following Table 7. Operating System upgrades outlines the hosts that should be upgraded:

Host	OS	EOL	Notes
PRTG	2012R2	10.10.2023	Update to Windows Server 2019
www	CentOS6	30.11.2020	Update to Centos 8.5
DC	2012R2	10.10.2023	Update to Windows Server 2019
Files	2008R2	14.1.2020	Update to Windows Server 2019
Dev-WS2	Xubuntu 20.04	29.4.2023	Update to Xubuntu 22.10

Legacy application	Windows 7	14.1.2020	Update to Windows
			Server 2019 or Windows
			10

Table 7. Operating System upgrades

In addition, the following hosts seen in Table 8 should have the service packages updated if deemed possible. Such updates should be done due to May 2023.

Host	os	Service to be updated
Firewall-ext	PANOS	Firewall
Firewall-int	PANOS	Firewall
SIEM	CentOS7	ElasticSIEM
Elasticsearch1	CentOS7	Elasticsearch
Elasticsearch2	CentOS7	Elasticsearch
Elasticsearch3	CentOS7	Elasticsearch
ntp	CentOS7	Chrony
ns1 & ns2	CentOS7	Bind
Extranet	CentOS8	WordPress

Mail	CentOS7	Postfix + Dovecot +
		Roundcubemail
Helpdesk	CentOS7	Zammad
Intra	CentOS8	WordPress
SQL	CentOS7	MySQL
SimpleCA	CentOS7	Custom
Proxy	CentOS7	Squid
Gitlab	CentOS8	Gitlab
HR	CentOS7	OrangeHRM

Table 8. Service updates

7.2 Microsoft Defender for Endpoint & cloud

The company has ongoing negotiations with Microsoft to update the endpoint detection and response system from FireEye to Microsoft Defender for Endpoint. In addition, the company is moving from local hosted services to cloud and is choosing to use Microsoft as the provider. The company is going to move to *Office 365* to use Office tools suite and Exchange. For hosting other services, the company is currently choosing between Azure and AWS. The upgrades should be done before June 2023.

7.3 SELinux & AppArmor

The company is going to enable SELinux and AppArmor security controls for the *nix systems. Such security controls could prevent escalating privileges on such systems if the attacker has a foothold on them. The upgrades should be done before October 2023.

7.4 SSH key authentication

SSH public key authentication (SSH, 2023) is based on an algorithm. Two of the most common that are being used are RSA and DSA. Public key encryption algorithms work with two separate keys. These two keys form a pair called public key and private key.

The motivation for using public key authentication and not passwords is security. SSH key authentication provides cryptographic strength that even extremely complicated passwords cannot offer. SSH public key authentication allows the implementation of single sign-on across SSH servers.

SSH key authentication prevents brute-force attacks and if the server that uses SSH key authentication is compromised. There are no credentials at risk.

SSH key authentication will be used for every Linux endpoint in the company network. In addition to SSH key authentication, the Root access for all Linux endpoints will be configured to go through a PAM (Privileged Access Management) solution. The PAM solution will also rotate the SSH keys after every launched session.

7.5 Tier level authentication model

MSFT Red Forest vs PAM

Privileged Access Management (PAM) (Microsoft, 2023) and Microsoft's Red Forest (Microsoft, 2023) are two distinct concepts related to cybersecurity, specifically in the domain of identity and access management. Red Forest architecture became popular to combat rising cyber-attacks. However, while the Red Forest approach was promising in theory, it was a complex and costly solution. For this reason, Microsoft is not recommending Red Forest approach anymore and has instead recommending the use of PAM.

Red Forest overview

The Red Forest or ESAE (Enhanced Security Admin Environment) (Microsoft, 2023) idea is based on tiering and limiting exposure of Administrative or highly privileged credentials in a case of a credential theft attack. The purpose of the tiers is to protect systems with a set of buffer zones between full control (Tier 0) and the high-risk workstations that are being compromised regularly. The tier model is composed of three levels. Each level includes only administrative accounts and not any standard user accounts.

Tier levels

Tier 0 has direct administrative access to the Active Directory or Domain controllers and all the assets they have. Tier 0 is the most critical and sensitive tier as it can control all the other assets.

Tier 1 has control of server operating systems, cloud services and enterprise applications. The tier 1 administrative accounts have high privileged access as they can control servers and cloud services. By compromising a tier 1 administrative account, the attacker gains access to the servers and cloud services and can control enterprise services.

Tier 2 has control of user workstations and devices. Tier 2 administrator accounts have control of business assets like Help desk and support administrator. For this reason, they have access to user data across the enterprise.

PAM (Privileged Access Management)

Microsoft has recently (Year?) retired the Red Forest approach to addressing privileged access and privileged access escalation. The recommendation is to use PAM instead (Microsoft, 2023) PAM is Privileged access management, and its aim is to implement least privileged and zero trust in enterprise environments. PAM can be implemented to cover most if not all modern enterprise use cases and most PAM products offer a wide variety of functionalities that cover everything from credential management to sessions launching, monitoring, and auditing.

PAM in target company for assignment

A PAM solution will be implemented in the environment, and it will be used for all access that can be considered privileged access. The PAM solution will be used for RDP and SSH connections for accessing administrative and root accounts on Windows and Linux servers. A password and SSH key rotation will be implemented to maximize security in the endpoints. HTTPS connections to services with administrative accounts will also be included in the PAM solution.

7.6 Logging

Company uses Elasticsearch and Kibana from ELK stack to apply logging to environment activities. Elasticsearch is a search and analytics engine used for storing and indexing logs. Kibana is a visualization tool used for querying and analyzing log data through a web interface. The ELK stack is commonly used for various use cases, such as troubleshooting, security analysis, and business intelligence (Elasticsearch B.V., n.d.).

Log collecting and shipping is implemented via Beats. Beats is an open-source platform for collecting, shipping, and processing data in real-time. It is composed of lightweight data shippers that can be installed on various sources, such as servers, containers, and IoT devices, to collect and forward data to a centralized location. The data can then be processed and analyzed by various backends, such as Elasticsearch, Logstash, or Kibana. Beats include various modules, such as Filebeat for collecting log files, Metricbeat for collecting system metrics, and Packetbeat for analyzing network traffic. The platform is commonly used for various use cases, such as monitoring, security, and application performance management (Elasticsearch B.V., n.d.).

The company will expand its current logging policies to affect all systems within its network. Current logging status can be reviewed in this report's attachment which includes information about what Beat-agents are used, in which systems those are installed and what modules are enabled within them.

During the review of the environment, it was observed that in all the configuration files of the ELK-stack the master credentials for the log system were stored in clear text. The Company can either implement API-key authentication or change the authentication credentials to some less privileged ones. The credentials being used are suitable for setting up the environment but should not be used in production. Kibana will also be configured with additional credentials for viewing log data instead of using the master credentials.

In addition, it was observed that Beat-agent configurations were not using SSL-verification when connecting to Elasticsearch nodes. The company will change the configurations of installed agents and enable SSL.

						A local privilege escalation								
						vulnerability was found on polkit's pkexec utility. The								
						pkexec application is a setuid								
						tool designed to allow unprivileged users to run								
						unprivileged users to run commands as privileged users according predefined policies.								
						The current version of pkexec doesn't handle the calling								
						doesn't handle the calling								
						parameters count correctly and ends trying to execute								
						environment variables as commands. An attacker can								
						leverage this by crafting environment variables in such								
						a way it'll induce pkexec to								
						execute arbitrary code. When successfully executed the								
						successfully executed the attack can cause a local								
						privilege escalation given unprivileged users
